Finally, we reveal that the diversity of striped patterns plays a key role for species recognition. Moreover, since interactions between individuals of different species can also be incorporated into these models, community-level properties can also potentially be explained by IBMs.

The cohabitation of different clownfish species in the same sea anemone host may also support this hypothesis. Given the realities of various field settings, how do laboratory environments really compare with respect to promotion of psychological well-being? Are striped patterns used for species recognition? However, ecological systems are supposed to have histories that result in highly contingent structures—part of their complexity—that make them special. Polygons need not have the same size or geometry.

Animal Homes and Habitats

The question of reductionism in ecology will be briefly discussed in this entry.

At an experimental level, animals may also be given specific challenges to look at their coping reactions. Strong winds and underwater formations, including the sills at Admiralty Inlet and Tacoma Narrows, interact with the tides to facilitate mixing between the layers, making nutrients available for phytoplankton.
