#### Laboratory safety

Population-based COVID-19—associated hospitalization rates among adolescents were lower than were those in adults, a finding consistent with studies showing that illness is generally milder in children than in adults 6.

#### HIRL

On any given day, about one in 31 hospital patients has at least one healthcare-associated infection.

#### Laboratory safety

One explanation for the large number of reported cases of laboratory-acquired shigellosis is that Shigella species are more virulent and require a much lower inoculum to cause illness. No other potential conflicts of interest were disclosed. What are the conclusions from clinical trials or meta-analyses regarding laboratory safety that guide infection control practices and policies? Share this Have you found the page useful? Most COVID-19—associated hospitalizations occur in adults, but severe disease occurs in all age groups, including adolescents aged 12—17 years.

## Laboratories and Research Projects

In a report from Canada, 26 laboratory workers were exposed to Brucella melitensis, which had been isolated from a patient from India with a draining chest sinus. This case brings the number of cases of bioterrorism-related anthrax identified since 3 October 2001 to 23 and is the first laboratory-acquired case of bioterrorism-related anthrax.
