Predicting New Zealand riverine fish reference assemblages [PeerJ]

New Zealand Journal of Marine and Freshwater Research 25, 81—91 Rowe DK and Chisnall BL 1995 Effects of oxygen, temperature and light gradients on the vertical distribution of rainbow trout, Oncorhynchus mykiss, in two North Island, New Zealand, lakes differing in trophic status. For the new model, growth data were obtained for an additional 130

trout bred from wild parents and kept in tanks at five constant temperatures range ± 0 . Although levels of concern for the status of shortfin eels are not similar, both customary and commercial harvests of this species are almost exclusively of females; this fact alone means that the fishery must be closely monitored and managed to ensure that there is no similar decline in stocks.

Freshwater eels in New Zealand: Eels

In addition, the annual congregation of juvenile eels elvers below hydrostations is now monitored through joint initiatives between the eel industry and fishery managers. The impact of stratification on the size and location of suitable brown trout habitat was modelled for a large impoundment.

A review of the flow and flow

Habitat Previous habitat preference investigations suggest that oxygen and temperature influence the available lake habitat to trout Rowe and Chisnall 1995.
